

CSET 335-Deep Learning Overview

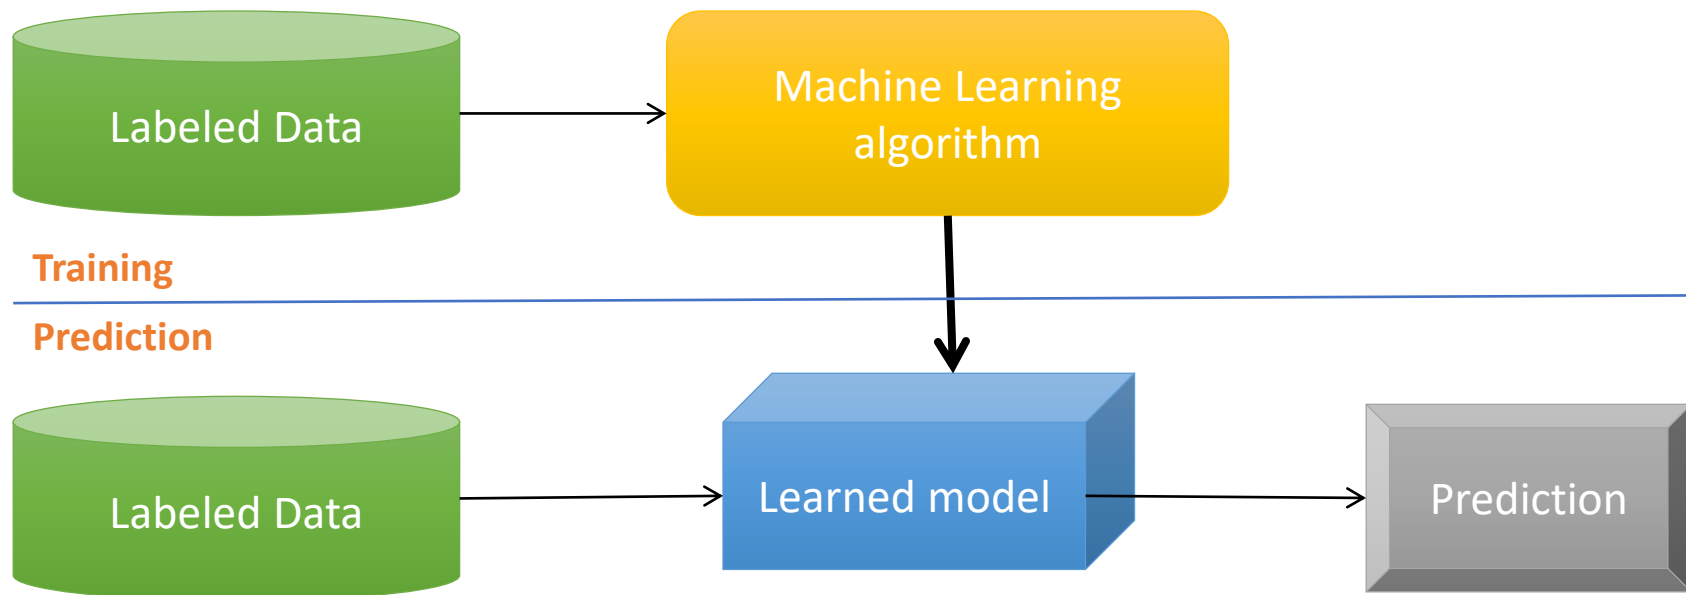

Lecture Outline

- Machine learning basics
 - Supervised and unsupervised learning
 - Linear and non-linear classification methods
- Introduction to deep learning
- Elements of neural networks (NNs)
 - Activation functions
- Training NNs
 - Gradient descent
 - Regularization methods
- NN architectures
 - Convolutional NNs
 - Recurrent NNs

Machine Learning Basics

Machine Learning Basics

- **Artificial Intelligence** is a scientific field concerned with the development of algorithms that allow computers to learn without being explicitly programmed
- **Machine Learning** is a branch of Artificial Intelligence, which focuses on methods that learn from data and make predictions on unseen data

Machine Learning Types

Machine Learning Basics

- **Supervised**: learning with **labeled data**
 - Example: email classification, image classification
 - Example: regression for predicting real-valued outputs
- **Unsupervised**: discover patterns in **unlabeled data**
 - Example: cluster similar data points
- **Reinforcement learning**: learn to act based on **feedback/reward**
 - Example: learn to play Go

Supervised Learning

Machine Learning Basics

- **Supervised learning** categories and techniques
 - **Numerical classifier functions**
 - Linear classifier, perceptron, logistic regression, support vector machines (SVM), neural networks
 - **Parametric (probabilistic) functions**
 - Naïve Bayes, Gaussian discriminant analysis (GDA), hidden Markov models (HMM), probabilistic graphical models
 - **Non-parametric (instance-based) functions**
 - k -nearest neighbors, kernel regression, kernel density estimation, local regression
 - **Symbolic functions**
 - Decision trees, classification and regression trees (CART)
 - **Aggregation (ensemble) learning**
 - Bagging, boosting (Adaboost), random forest

Unsupervised Learning

Machine Learning Basics

- **Unsupervised learning** categories and techniques
 - **Clustering**
 - k -means clustering
 - Mean-shift clustering
 - Spectral clustering
 - **Density estimation**
 - Gaussian mixture model (GMM)
 - Graphical models
 - **Dimensionality reduction**
 - Principal component analysis (PCA)
 - Factor analysis

Nearest Neighbor Classifier

Machine Learning Basics

- **Nearest Neighbor** – for each test data point, assign the class label of the nearest training data point
 - Adopt a distance function to find the nearest neighbor
 - Calculate the distance to each data point in the training set, and assign the class of the nearest data point (minimum distance)
 - It does not require learning a set of weights

Nearest Neighbor Classifier

Machine Learning Basics

- For image classification, the distance between all pixels is calculated (e.g., using ℓ_1 norm, or ℓ_2 norm)
 - Accuracy on CIFAR-10: 38.6%
- Disadvantages:
 - The classifier must remember all training data and store it for future comparisons with the test data
 - Classifying a test image is expensive since it requires a comparison to all training images

test image					training image					pixel-wise absolute value differences			
56	32	10	18	-	10	20	24	17	=	46	12	14	1
90	23	128	133		8	10	89	100		82	13	39	33
24	26	178	200		12	16	178	170		12	10	0	30
2	0	255	220		4	32	233	112		2	32	22	108

→ 456

ℓ_1 norm
(Manhattan distance)

$$d_1(I_1, I_2) = \sum_p |I_1^p - I_2^p|$$

k -Nearest Neighbors Classifier

Machine Learning Basics

- **k -Nearest Neighbors** approach considers multiple neighboring data points to classify a test data point
 - E.g., 3-nearest neighbors
 - The test example in the figure is the + mark
 - The class of the test example is obtained by voting (based on the distance to the 3 closest points)

Linear Classifier

Machine Learning Basics

- *Linear classifier*

- Find a linear function f of the inputs x_i that separates the classes

$$f(x_i, W, b) = Wx_i + b$$

- Use pairs of inputs and labels to find the **weights matrix** W and the **bias vector** b
 - The weights and biases are the **parameters** of the function f
- Several methods have been used to find the optimal set of parameters of a linear classifier
 - A common method of choice is the *Perceptron* algorithm, where the parameters are updated until a minimal error is reached (single layer, does not use backpropagation)
- Linear classifier is a simple approach, but it is a building block of advanced classification algorithms, such as SVM and neural networks
 - Earlier multi-layer neural networks were referred to as multi-layer perceptrons (MLPs)

Linear Classifier

Machine Learning Basics

- The **decision boundary** is linear
 - A straight line in 2D, a flat plane in 3D, a **hyperplane** in 3D and higher dimensional space
- Example: classify an input image
 - The selected parameters in this example are not good, because the predicted cat score is low

Support Vector Machines

Machine Learning Basics

- **Support vector machines (SVM)**
 - How to find the best decision boundary?
 - All lines in the figure correctly separate the 2 classes
 - The line that is farthest from all training examples will have better generalization capabilities
 - SVM solves an optimization problem:
 - First, identify a **decision boundary** that correctly classifies the examples
 - Next, increase the geometric margin between the boundary and all examples
 - The data points that define the maximum margin width are called **support vectors**
 - Find W and b by solving:

$$\min \frac{1}{2} \|w\|^2$$

$$s.t. y_i(w \cdot x_i + b) \geq 1, \forall x_i$$

Linear vs Non-linear Techniques

Linear vs Non-linear Techniques

- Linear classification techniques
 - Linear classifier
 - Perceptron
 - Logistic regression
 - Linear SVM
 - Naïve Bayes
- Non-linear classification techniques
 - k -nearest neighbors
 - Non-linear SVM
 - Neural networks
 - Decision trees
 - Random forest

Linear vs Non-linear Techniques

Linear vs Non-linear Techniques

- For some tasks, input data can be linearly separable, and linear classifiers can be suitably applied

- For other tasks, linear classifiers may have difficulties to produce adequate decision boundaries

Non-linear Techniques

Linear vs Non-linear Techniques

- Non-linear classification
 - Features z_i are obtained as **non-linear functions** of the inputs x_i
 - It results in non-linear decision boundaries
 - Can deal with non-linearly separable data

Inputs: $x_i = [x_{n1} \quad x_{n2}]$

Features: $z_i = [x_{n1} \quad x_{n2} \quad x_{n1} \cdot x_{n2} \quad x_{n1}^2 \quad x_{n2}^2]$

Outputs: $f(x_i, W, b) = Wz_i + b$

Non-linear Support Vector Machines

Linear vs Non-linear Techniques

- **Non-linear SVM**

- The original input space is mapped to a higher-dimensional feature space where the training set is linearly separable
- Define a non-linear kernel function to calculate a non-linear decision boundary in the original feature space

Binary vs Multi-class Classification

Binary vs Multi-class Classification

- A classification problem with only 2 classes is referred to as *binary classification*
 - The output labels are 0 or 1
 - E.g., benign or malignant tumor, spam or no-spam email
- A problem with 3 or more classes is referred to as *multi-class classification*

Binary vs Multi-class Classification

Binary vs Multi-class Classification

- Both the binary and multi-class classification problems can be linearly or non-linearly separated
 - Figure: linearly and non-linearly separated data for binary classification problem

Linear

Nonlinear

Computer Vision Tasks

Machine Learning Basics

- Computer vision has been the primary area of interest for ML
- The tasks include: classification, localization, object detection, instance segmentation

Classification

CAT

**Classification
+ Localization**

CAT

Object Detection

CAT, DOG, DUCK

Instance Segmentation

CAT, DOG, DUCK

Single object

Multiple objects

No-Free-Lunch Theorem

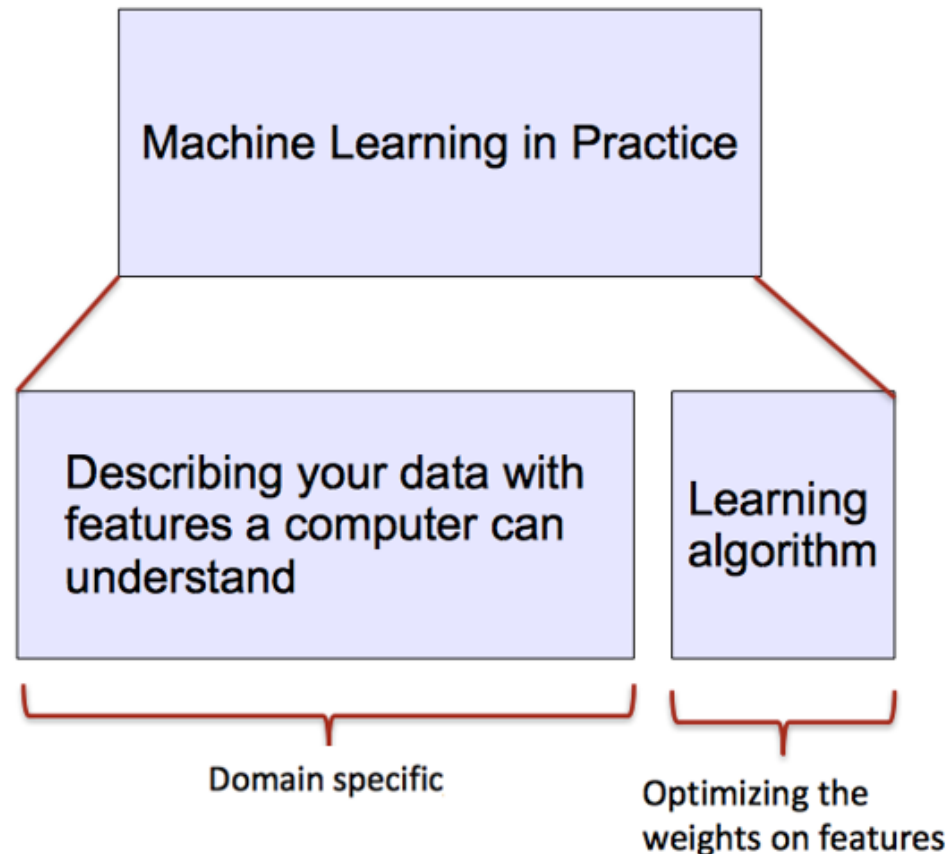

Machine Learning Basics

- [Wolpert \(2002\) - The Supervised Learning No-Free-Lunch Theorems](#)
- The derived classification models for supervised learning are simplifications of the reality
 - The simplifications are based on certain assumptions
 - The assumptions fail in some situations
 - E.g., due to inability to perfectly estimate ML model parameters from limited data
- In summary, *No-Free-Lunch Theorem* states:
 - **No single classifier works the best for all possible problems**
 - Since we need to make assumptions to generalize

ML vs. Deep Learning

Introduction to Deep Learning

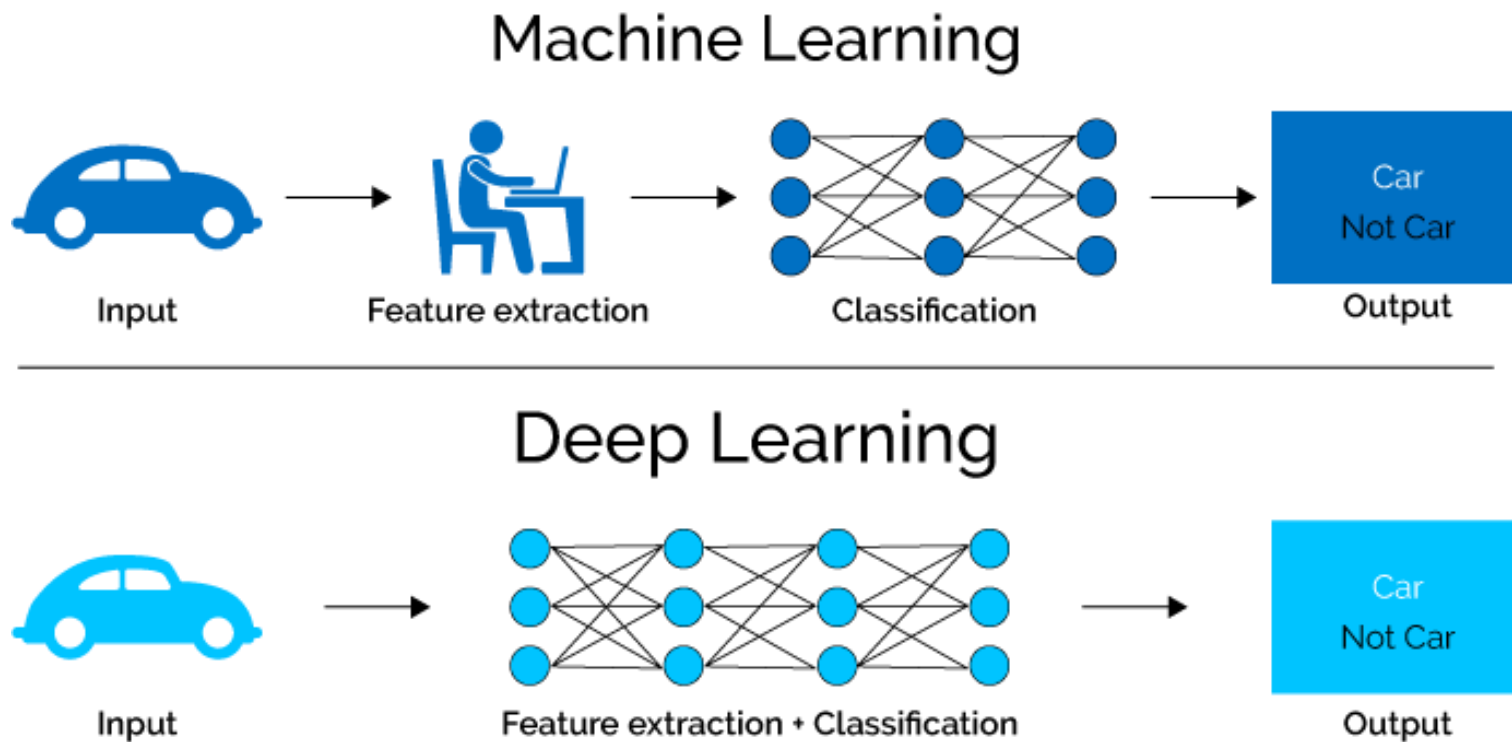

- Conventional machine learning methods rely on **human-designed feature representations**
 - ML becomes just optimizing weights to best make a final prediction

ML vs. Deep Learning

Introduction to Deep Learning

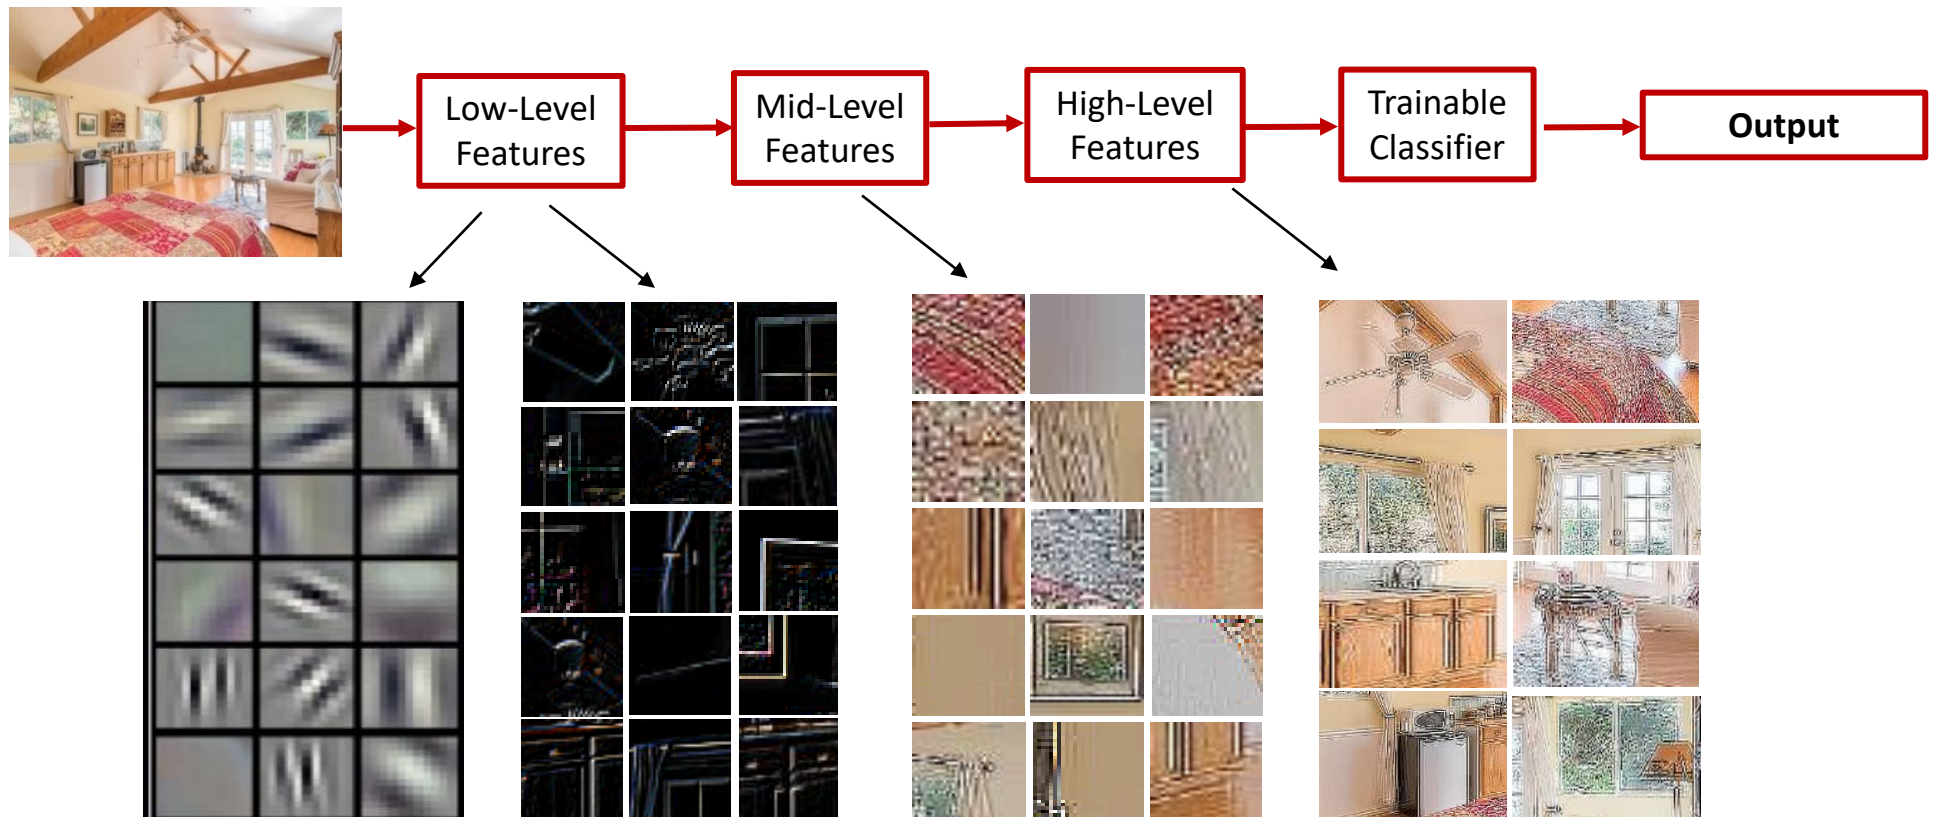

- **Deep learning** (DL) is a machine learning subfield that uses multiple layers for learning data representations
 - DL is exceptionally effective at learning patterns

ML vs. Deep Learning

Introduction to Deep Learning

- DL applies a multi-layer process for learning rich hierarchical features (i.e., data representations)
 - Input image pixels → Edges → Textures → Parts → Objects

Why is DL Useful?

Introduction to Deep Learning

- DL provides a flexible, learnable framework for representing visual, text, linguistic information
 - Can learn in supervised and unsupervised manner
- DL represents an effective end-to-end learning system
- Requires large amounts of training data
- Since about 2010, DL has outperformed other ML techniques
 - First in vision and speech, then NLP, and other applications

Representational Power

Introduction to Deep Learning

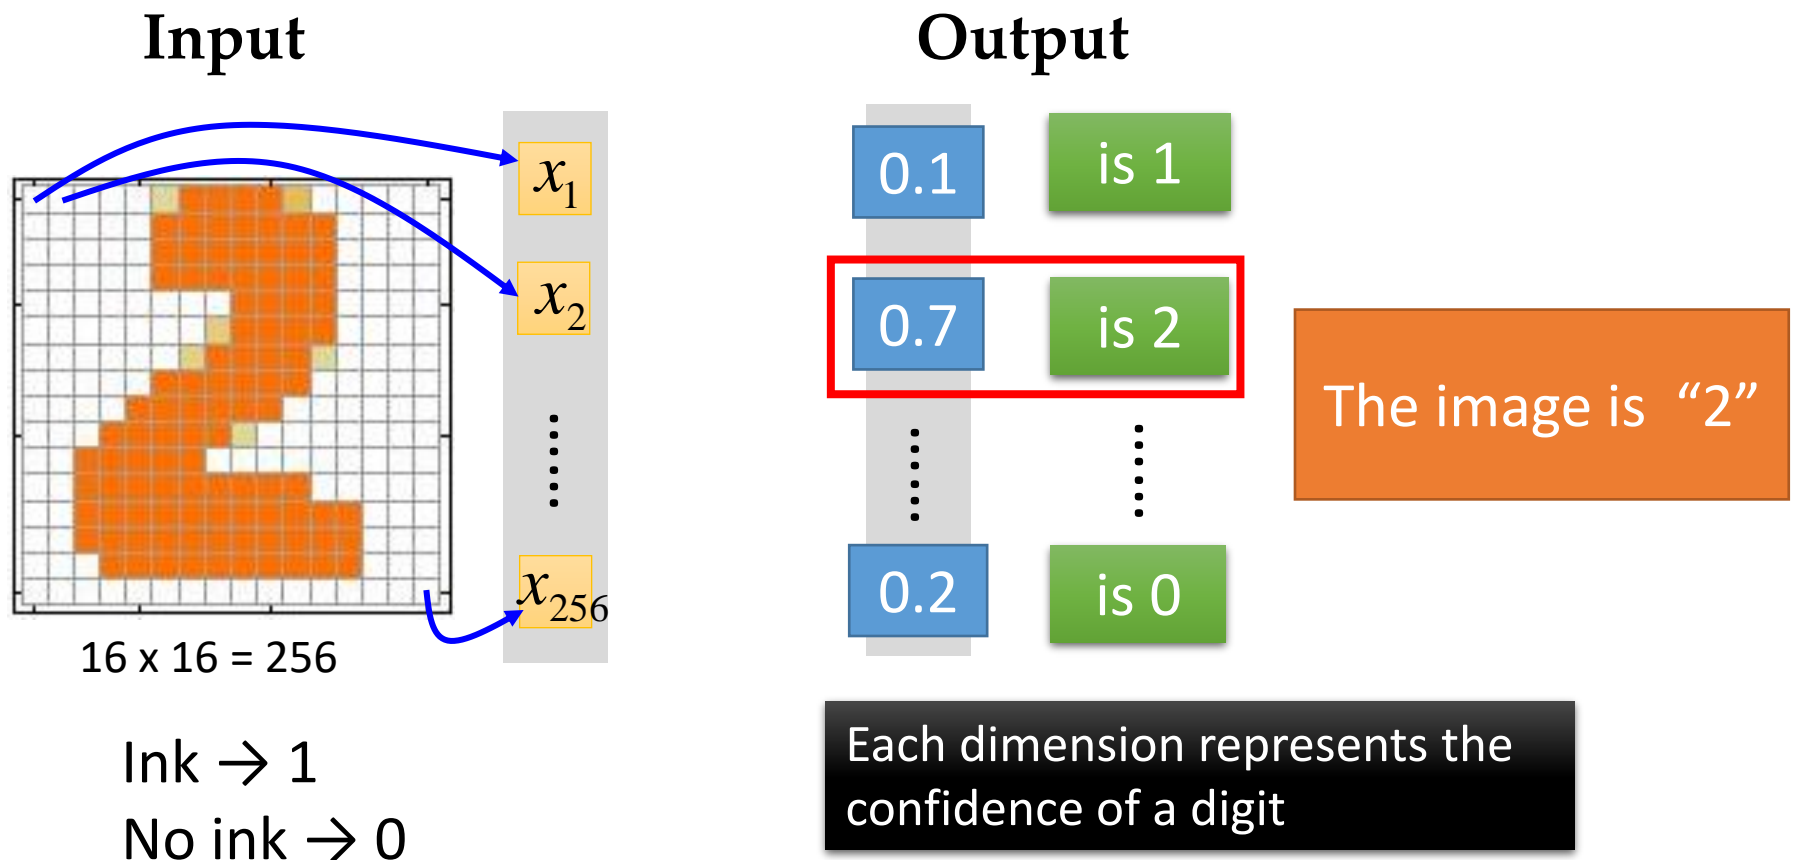

- NNs with at least one hidden layer are **universal approximators**
 - Given any continuous function $h(x)$ and some $\epsilon > 0$, there exists a NN with one hidden layer (and with a reasonable choice of non-linearity) described with the function $f(x)$, such that $\forall x, |h(x) - f(x)| < \epsilon$
 - I.e., NN can approximate any arbitrary complex continuous function
- NNs use nonlinear mapping of the inputs x to the outputs $f(x)$ to compute complex decision boundaries
- But then, why use deeper NNs?
 - The fact that deep NNs work better is an empirical observation
 - Mathematically, deep NNs have the same representational power as a one-layer NN

Introduction to Neural Networks

Introduction to Neural Networks

- Handwritten digit recognition (**MNIST dataset**)
 - The intensity of each pixel is considered an **input** element
 - **Output** is the class of the digit

Introduction to Neural Networks

Introduction to Neural Networks

- Handwritten digit recognition

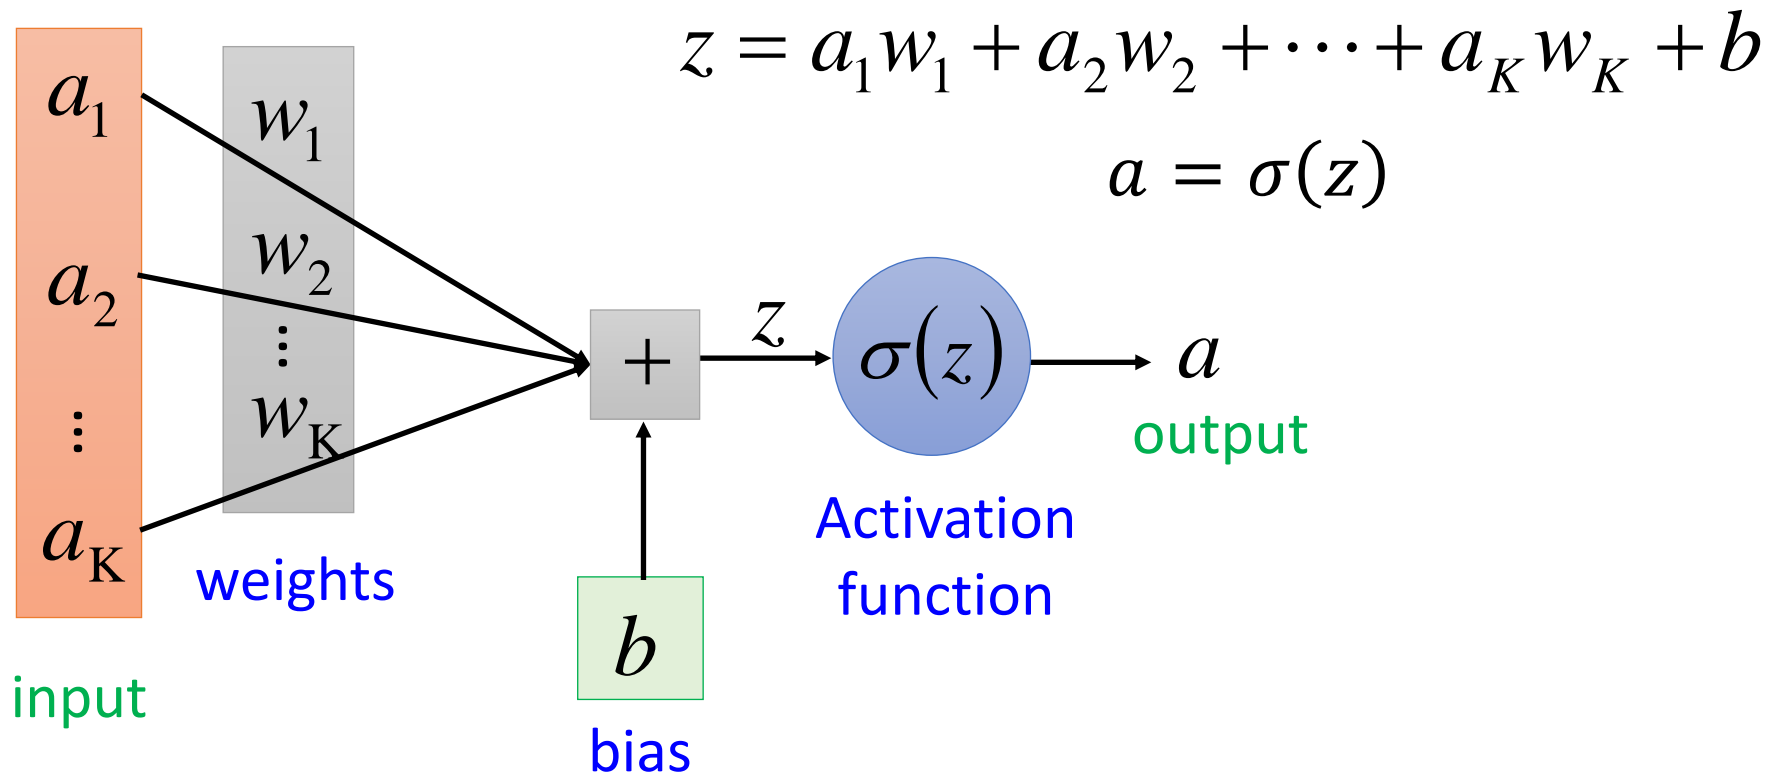

The function f is represented by a neural network

Elements of Neural Networks

Introduction to Neural Networks

- NNs consist of hidden layers with neurons (i.e., computational units)
- A single **neuron** maps a set of inputs into an output number, or $f: R^K \rightarrow R$

Elements of Neural Networks

Introduction to Neural Networks

- A NN with one hidden layer and one output layer

Weights Biases

$$\text{hidden layer } h = \sigma(W_1 x + b_1)$$
$$\text{output layer } y = \sigma(W_2 h + b_2)$$

Activation functions

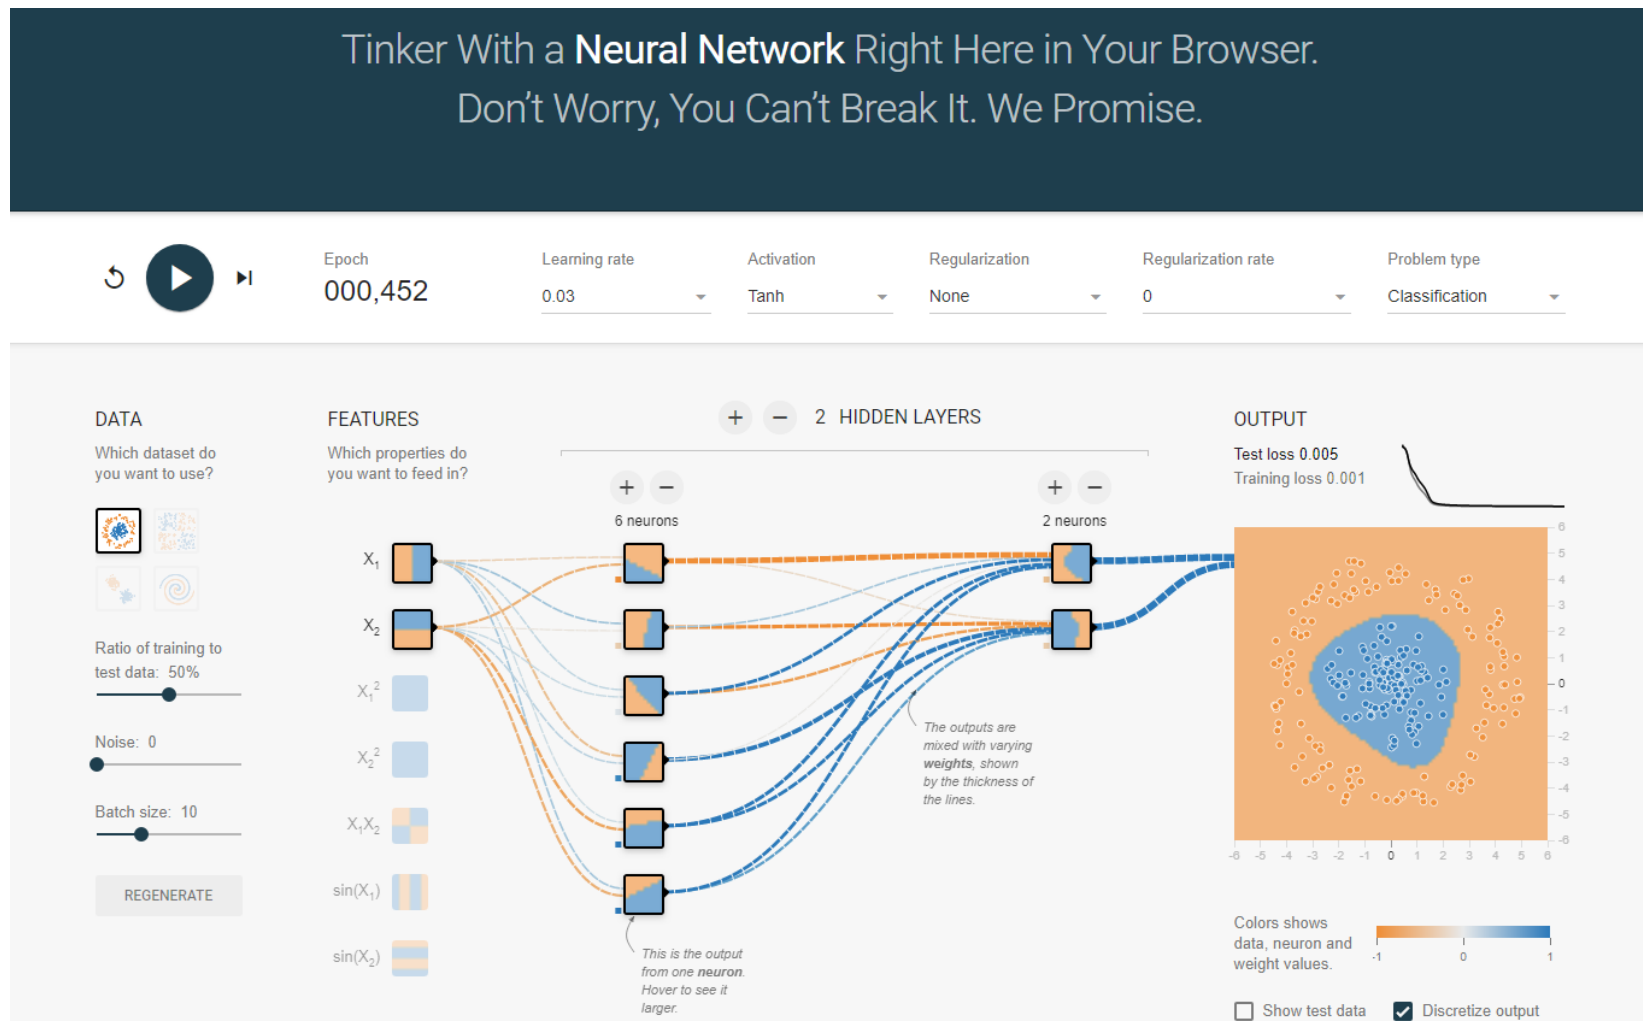

4 + 2 = 6 neurons (not counting inputs)
[3 × 4] + [4 × 2] = 20 weights
4 + 2 = 6 biases

26 learnable parameters

Elements of Neural Networks

Introduction to Neural Networks

- A neural network playground [link](#)

Elements of Neural Networks

Introduction to Neural Networks

- Deep NNs have many hidden layers
 - **Fully-connected (dense)** layers (a.k.a. **Multi-Layer Perceptron** or MLP)
 - Each neuron is connected to all neurons in the succeeding layer

Elements of Neural Networks

Introduction to Neural Networks

- A simple network, toy example

Sigmoid Function

$$\sigma(z) = \frac{1}{1 + e^{-z}}$$

Elements of Neural Networks

Introduction to Neural Networks

- A simple network, toy example (cont'd)
 - For an input vector $[1 \ -1]^T$, the output is $[0.62 \ 0.83]^T$

$$f: R^2 \rightarrow R^2 \quad f\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}\right) = \begin{bmatrix} 0.62 \\ 0.83 \end{bmatrix}$$

Matrix Operation

Introduction to Neural Networks

- Matrix operations are helpful when working with multidimensional inputs and outputs

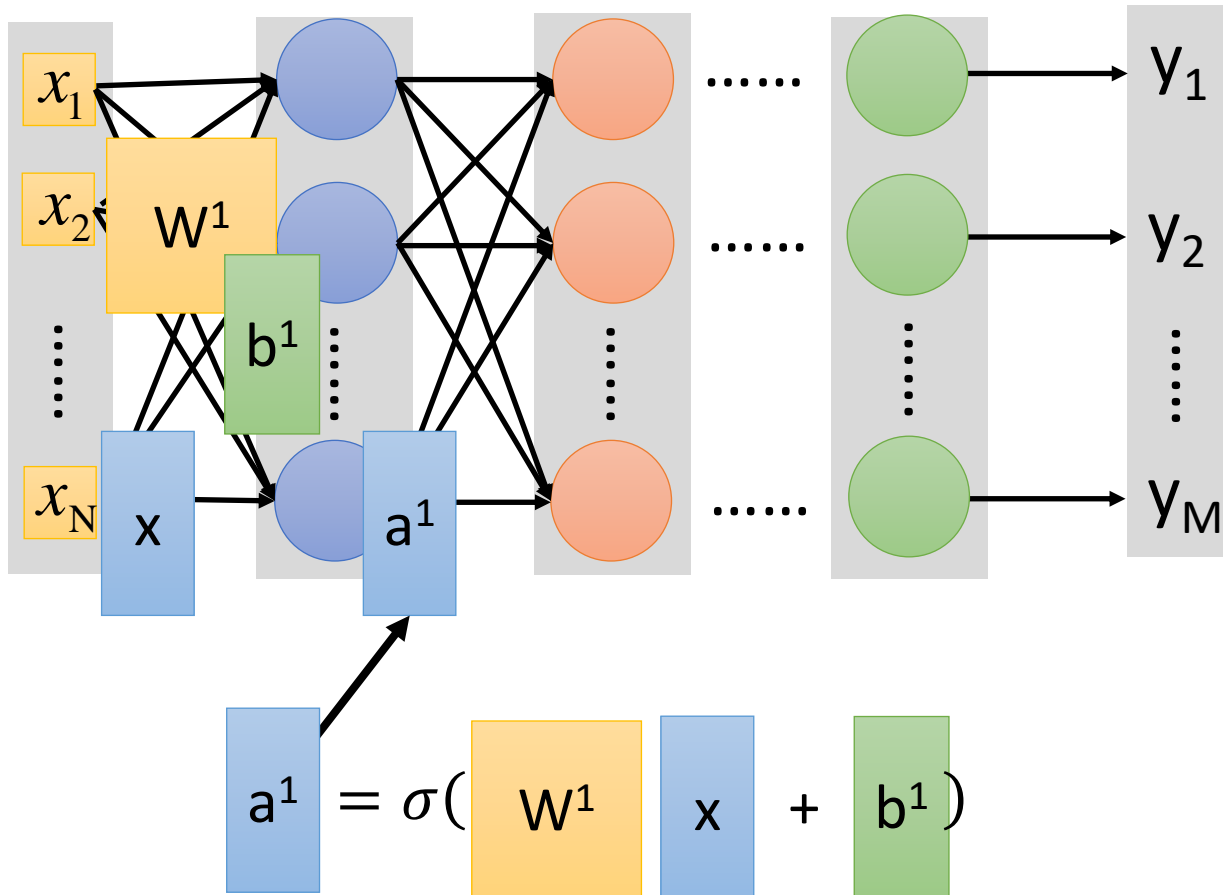

$$\sigma(\begin{bmatrix} W \end{bmatrix} \begin{bmatrix} x \end{bmatrix} + \begin{bmatrix} b \end{bmatrix}) = \begin{bmatrix} a \end{bmatrix}$$

$$\sigma(\underbrace{\begin{bmatrix} 1 & -2 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix}}_{\begin{bmatrix} 4 \\ -2 \end{bmatrix}}) = \begin{bmatrix} 0.98 \\ 0.12 \end{bmatrix}$$

Matrix Operation

Introduction to Neural Networks

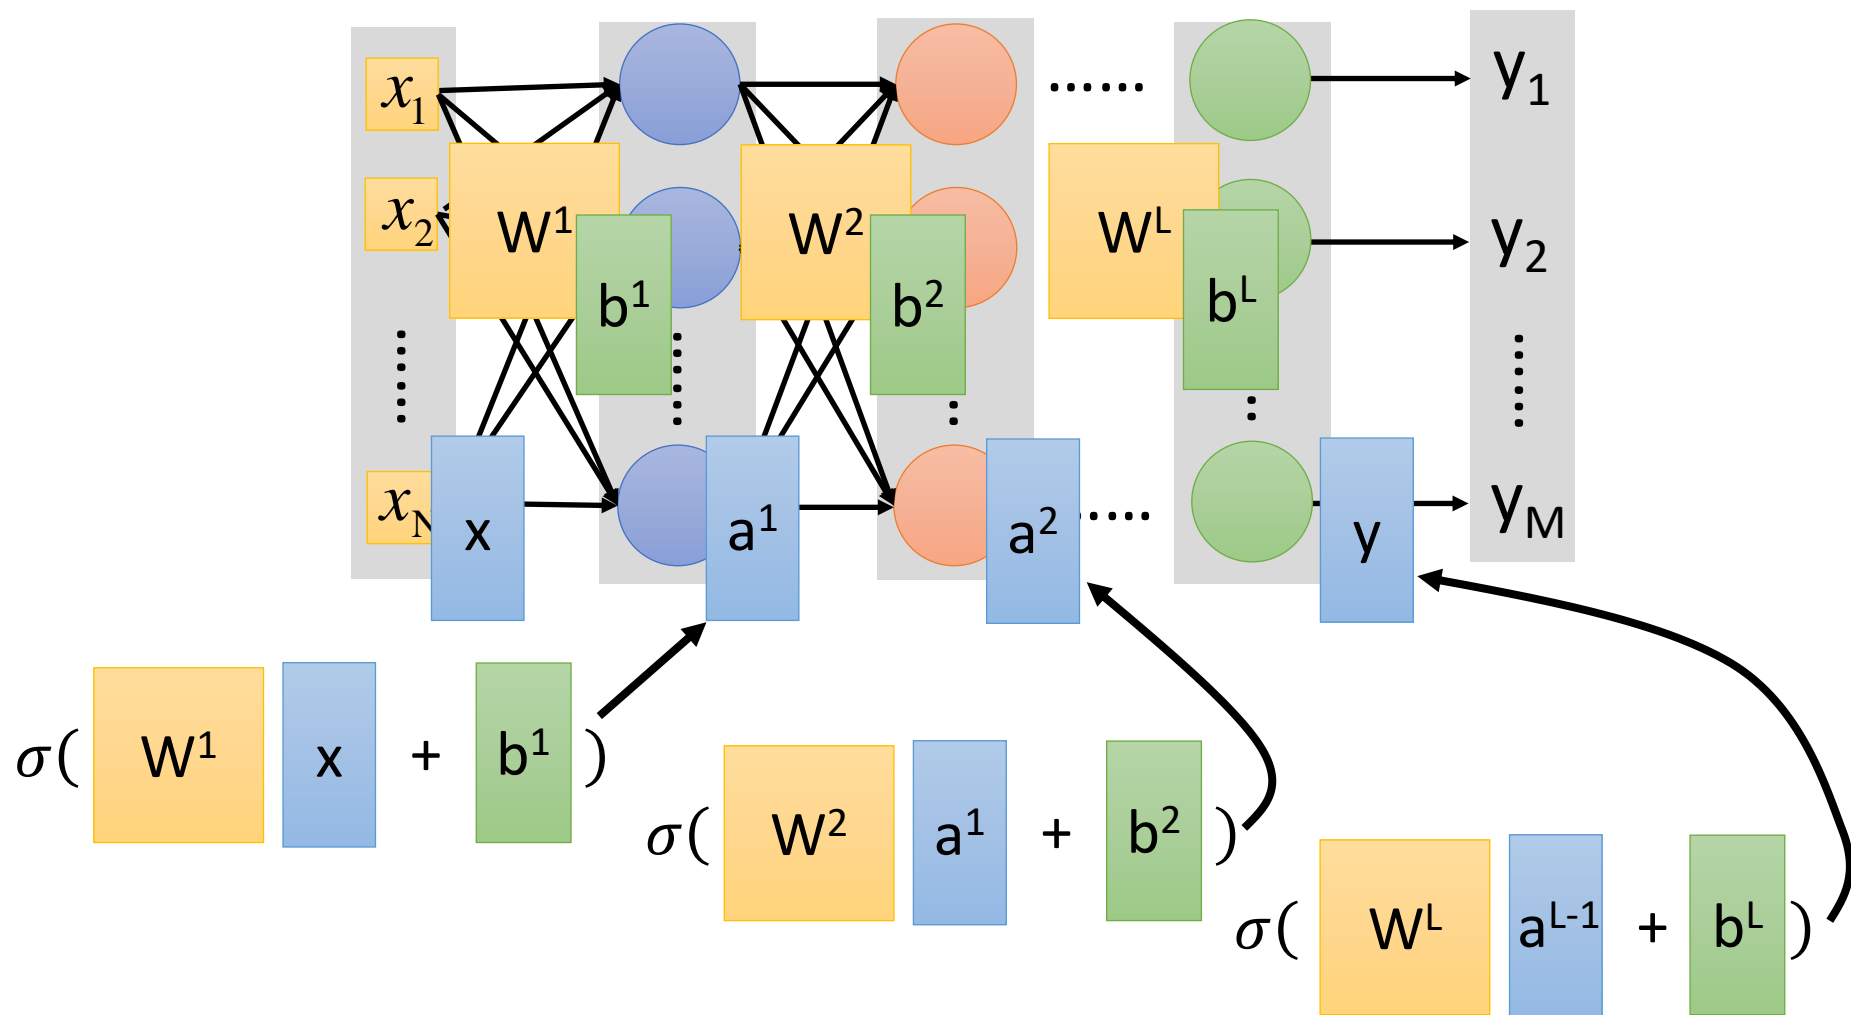

- Multilayer NN, matrix calculations for the first layer
 - Input vector x , weights matrix W^1 , bias vector b^1 , output vector a^1

Matrix Operation

Introduction to Neural Networks

- Multilayer NN, matrix calculations for all layers

Matrix Operation

Introduction to Neural Networks

- Multilayer NN, function f maps inputs x to outputs y , i.e., $y = f(x)$

$$y = f(x) = \sigma(W^L \dots \sigma(W^2 \sigma(W^1 x + b^1) + b^2) \dots + b^L)$$

Softmax Layer

Introduction to Neural Networks

- In **multi-class classification** tasks, the output layer is typically a *softmax layer*
 - I.e., it employs a *softmax activation function*
 - If a layer with a sigmoid activation function is used as the output layer instead, the predictions by the NN may not be easy to interpret
 - Note that an output layer with sigmoid activations can still be used for binary classification

A Layer with Sigmoid Activations

Softmax Layer

Introduction to Neural Networks

- The **softmax layer** applies softmax activations to output a probability value in the range $[0, 1]$
 - The values z inputted to the softmax layer are referred to as *logits*

Probability:

- $0 < y_i < 1$
- $\sum_i y_i = 1$

A Softmax Layer

Activation Functions

Introduction to Neural Networks

- **Non-linear activations** are needed to learn complex (non-linear) data representations
 - Otherwise, NNs would be just a linear function (such as $W_1 W_2 x = Wx$)
 - NNs with large number of layers (and neurons) can approximate more complex functions
 - Figure: more neurons improve representation (but, may overfit)

Activation: Sigmoid

Introduction to Neural Networks

- **Sigmoid function** σ : takes a real-valued number and “squashes” it into the range between 0 and 1
 - The output can be interpreted as the firing rate of a biological neuron
 - Not firing = 0; Fully firing = 1
 - When the neuron’s activation are 0 or 1, sigmoid neurons saturate
 - Gradients at these regions are almost zero (almost no signal will flow)
 - Sigmoid activations are less common in modern NNs

Activation: Tanh

Introduction to Neural Networks

- **Tanh function**: takes a real-valued number and “squashes” it into range between -1 and 1
 - Like sigmoid, tanh neurons saturate
 - Unlike sigmoid, the output is zero-centered
 - It is therefore preferred than sigmoid
 - Tanh is a scaled sigmoid: $\tanh(x) = 2 \cdot \sigma(2x) - 1$

$$\mathbb{R}^n \rightarrow [-1,1]$$

Activation: ReLU

Introduction to Neural Networks

- **ReLU** (Rectified Linear Unit): takes a real-valued number and thresholds it at zero

$$f(x) = \max(0, x)$$

- Most modern deep NNs use ReLU activations
- ReLU is fast to compute
 - Compared to sigmoid, tanh
 - Simply threshold a matrix at zero
- Accelerates the convergence of gradient descent
 - Due to linear, non-saturating form
- Prevents the gradient vanishing problem

Activation: Leaky ReLU

Introduction to Neural Networks

- The problem of ReLU activations: they can “die”
 - ReLU could cause weights to update in a way that the gradients can become zero and the neuron will not activate again on any data
 - E.g., when a large learning rate is used
- **Leaky ReLU** activation function is a variant of ReLU
 - Instead of the function being 0 when $x < 0$, a leaky ReLU has a small negative slope (e.g., $\alpha = 0.01$, or similar)
 - This resolves the dying ReLU problem
 - Most current works still use ReLU
 - With a proper setting of the learning rate, the problem of dying ReLU can be avoided

Activation: Linear Function

Introduction to Neural Networks

- **Linear function** means that the output signal is proportional to the input signal to the neuron
 - If the value of the constant c is 1, it is also called **identity activation function**
 - This activation type is used in regression problems
 - E.g., the last layer can have linear activation function, in order to output a real number (and not a class membership)

Training NNs

Training Neural Networks

- The network *parameters* θ include the **weight matrices** and **bias vectors** from all layers

$$\theta = \{W^1, b^1, W^2, b^2, \dots, W^L, b^L\}$$

- Often, the model parameters θ are referred to as **weights**
- Training a model to learn a set of parameters θ that are optimal (according to a criterion) is one of the greatest challenges in ML

Training NNs

Training Neural Networks

- **Data preprocessing** - helps convergence during training
 - **Mean subtraction**, to obtain zero-centered data
 - Subtract the mean for each individual data dimension (feature)
 - **Normalization**
 - Divide each feature by its standard deviation
 - To obtain standard deviation of 1 for each data dimension (feature)
 - Or, scale the data within the range $[0,1]$ or $[-1, 1]$
 - E.g., image pixel intensities are divided by 255 to be scaled in the $[0,1]$ range

Training NNs

Training Neural Networks

- To train a NN, set the parameters θ such that for a training subset of images, the corresponding elements in the predicted output have maximum values

Training NNs

Training Neural Networks

- Define a **loss function/objective function/cost function** $\mathcal{L}(\theta)$ that calculates the difference (error) between the model prediction and the true label
 - E.g., $\mathcal{L}(\theta)$ can be mean-squared error, cross-entropy, etc.

Training NNs

Training Neural Networks

- For a training set of N images, calculate the total loss overall all images: $\mathcal{L}(\theta) = \sum_{n=1}^N \mathcal{L}_n(\theta)$
- Find the optimal parameters θ^* that minimize the total loss $\mathcal{L}(\theta)$

Loss Functions

Training Neural Networks

- *Classification tasks*

**Training
examples**

Pairs of N inputs x_i and ground-truth class labels y_i

**Output
Layer**

Softmax Activations
[maps to a probability distribution]

$$P(y = j \mid \mathbf{x}) = \frac{e^{\mathbf{x}^\top \mathbf{w}_j}}{\sum_{k=1}^K e^{\mathbf{x}^\top \mathbf{w}_k}}$$

Loss function

Cross-entropy $\mathcal{L}(\theta) = -\frac{1}{N} \sum_{i=1}^N \sum_{k=1}^K \left[y_k^{(i)} \log \hat{y}_k^{(i)} + (1 - y_k^{(i)}) \log (1 - \hat{y}_k^{(i)}) \right]$

Ground-truth class labels y_i and model predicted class labels \hat{y}_i

Loss Functions

Training Neural Networks

- *Regression tasks*

**Training
examples**

Pairs of N inputs x_i and ground-truth output values y_i

**Output
Layer**

Linear (Identity) or Sigmoid Activation

Loss function

Mean Squared Error $\mathcal{L}(\theta) = \frac{1}{n} \sum_{i=1}^n (y^{(i)} - \hat{y}^{(i)})^2$

Mean Absolute Error $\mathcal{L}(\theta) = \frac{1}{n} \sum_{i=1}^n |y^{(i)} - \hat{y}^{(i)}|$

Training NNs

Training Neural Networks

- Optimizing the loss function $\mathcal{L}(\theta)$
 - Almost all DL models these days are trained with a variant of the *gradient descent* (GD) algorithm
 - GD applies iterative refinement of the network **parameters θ**
 - GD uses the opposite direction of the **gradient** of the loss with respect to the NN parameters (i.e., $\nabla \mathcal{L}(\theta) = [\partial \mathcal{L} / \partial \theta_i]$) for updating θ
 - The gradient of the loss function $\nabla \mathcal{L}(\theta)$ gives the direction of fastest increase of the loss function $\mathcal{L}(\theta)$ when the parameters θ are changed

Gradient Descent Algorithm

Training Neural Networks

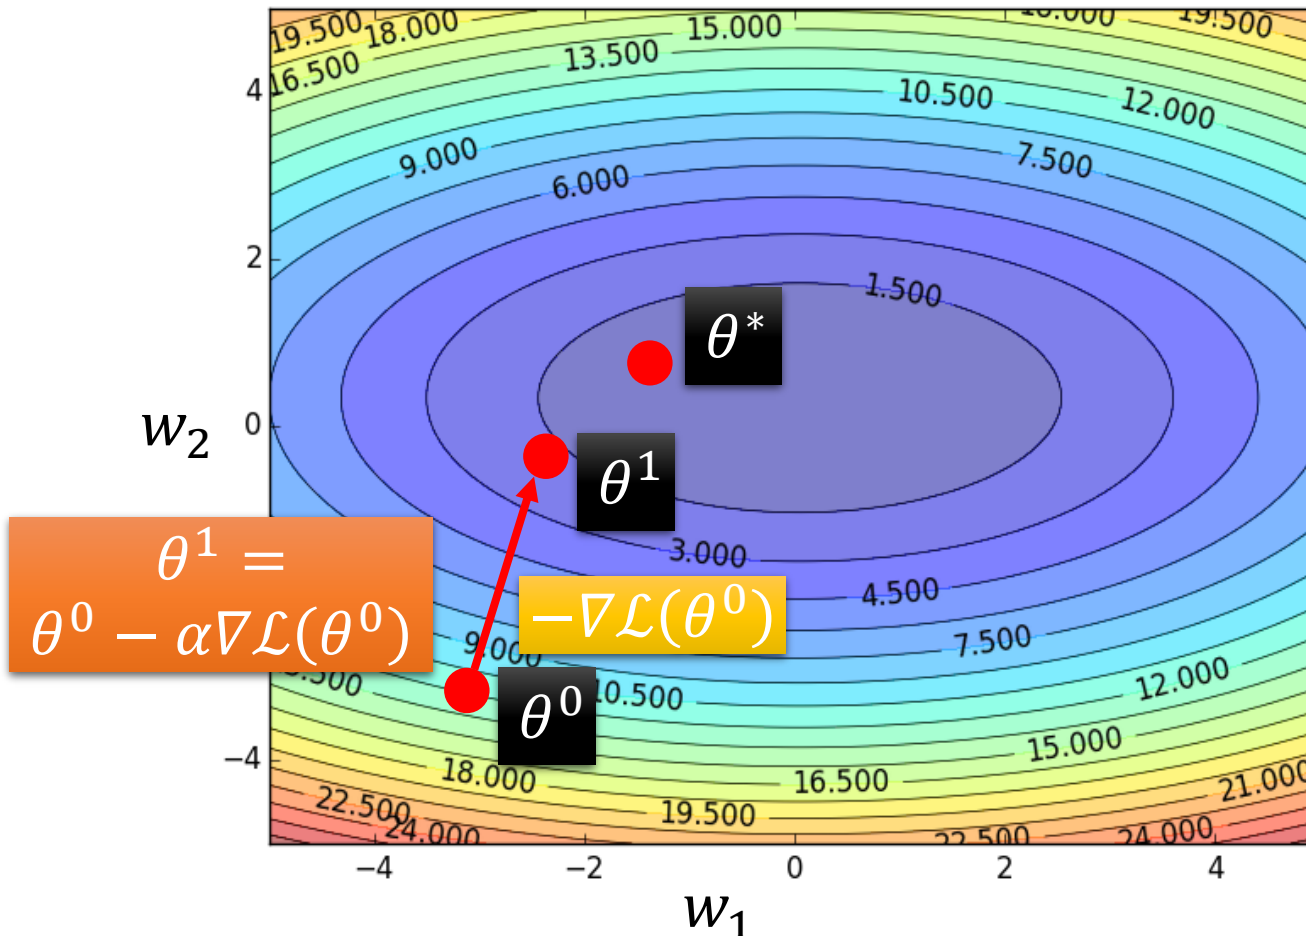

- Steps in the *gradient descent algorithm*:
 1. Randomly initialize the model parameters, θ^0
 2. Compute the gradient of the loss function at the initial parameters θ^0 : $\nabla\mathcal{L}(\theta^0)$
 3. Update the parameters as: $\theta^{new} = \theta^0 - \alpha\nabla\mathcal{L}(\theta^0)$
 - Where α is the learning rate
 4. Go to step 2 and repeat (until a terminating criterion is reached)

Gradient Descent Algorithm

Training Neural Networks

- Example: a NN with only 2 parameters w_1 and w_2 , i.e., $\theta = \{w_1, w_2\}$
 - The different colors represent the values of the loss (minimum loss θ^* is ≈ 1.3)

1. Randomly pick a starting point θ^0
2. Compute the gradient at θ^0 , $\nabla \mathcal{L}(\theta^0)$
3. Times the learning rate η , and update θ ,
 $\theta^{new} = \theta^0 - \alpha \nabla \mathcal{L}(\theta^0)$
4. Go to step 2, repeat

$$\nabla \mathcal{L}(\theta^0) = \begin{bmatrix} \partial \mathcal{L}(\theta^0) / \partial w_1 \\ \partial \mathcal{L}(\theta^0) / \partial w_2 \end{bmatrix}$$

Gradient Descent Algorithm

Training Neural Networks

- Example (contd.)

Eventually, we would reach a minimum

2. Compute the gradient at θ^{old} , $\nabla \mathcal{L}(\theta^{old})$

3. Times the learning rate η , and update θ ,
$$\theta^{new} = \theta^{old} - \alpha \nabla \mathcal{L}(\theta^{old})$$

4. Go to step 2, repeat

Gradient Descent Algorithm

Training Neural Networks

- Gradient descent algorithm stops when a **local minimum** of the loss surface is reached
- Gradient descent (GD) is an iterative first-order optimization algorithm, used to find a local minimum/maximum of a given function. This method is commonly used in machine learning (ML) and deep learning (DL) to minimize a cost/loss function (e.g. in a linear regression).
 - GD does not guarantee reaching a **global minimum**
 - However, empirical evidence suggests that GD works well for NNs

Gradient Descent Algorithm

Training Neural Networks

- For most tasks, the **loss surface** $\mathcal{L}(\theta)$ is highly complex (and non-convex)
- Random initialization in NNs results in different initial parameters θ^0 every time the NN is trained
 - Gradient descent may reach different minima at every run
 - Therefore, NN will produce different predicted outputs
- In addition, currently we don't have algorithms that guarantee reaching a **global minimum** for an arbitrary loss function

Backpropagation

Training Neural Networks

- Modern NNs employ the **backpropagation** method for calculating the gradients of the loss function $\nabla \mathcal{L}(\theta) = \partial \mathcal{L} / \partial \theta_i$
 - Backpropagation is short for “backward propagation”
- For training NNs, **forward propagation** (forward pass) refers to passing the inputs x through the hidden layers to obtain the model outputs (predictions) y
 - The loss $\mathcal{L}(y, \hat{y})$ function is then calculated
 - **Backpropagation** traverses the network in reverse order, from the outputs y backward toward the inputs x to calculate the gradients of the loss $\nabla \mathcal{L}(\theta)$
 - The chain rule is used for calculating the partial derivatives of the loss function with respect to the parameters θ in the different layers in the network
- Each update of the model parameters θ during training takes one forward and one backward pass (e.g., of a batch of inputs)
- Automatic calculation of the gradients (**automatic differentiation**) is available in all current deep learning libraries
 - It significantly simplifies the implementation of deep learning algorithms, since it obviates deriving the partial derivatives of the loss function by hand

Mini-batch Gradient Descent

Training Neural Networks

- It is wasteful to compute the loss over the **entire training dataset** to perform a single parameter update for large datasets
 - E.g., ImageNet has 14M images
 - Therefore, GD (a.k.a. vanilla GD) is almost always replaced with mini-batch GD
- *Mini-batch gradient descent*
 - Approach:
 - Compute the loss $\mathcal{L}(\theta)$ on a mini-batch of images, update the parameters θ , and repeat until all images are used
 - At the next epoch, shuffle the training data, and repeat the above process
 - Mini-batch GD results in much faster training
 - Typical mini-batch size: 32 to 256 images
 - It works because the gradient from a mini-batch is a good approximation of the gradient from the entire training set

Stochastic Gradient Descent

Training Neural Networks

- *Stochastic gradient descent*
 - SGD uses mini-batches that consist of a **single input example**
 - E.g., one image mini-batch
 - Although this method is very fast, it may cause significant fluctuations in the loss function
 - Therefore, it is less commonly used, and mini-batch GD is preferred
 - In most DL libraries, SGD typically means a mini-batch GD (with an option to add momentum)

Problems with Gradient Descent

Training Neural Networks

- Besides the local minima problem, the GD algorithm can be very slow at **plateaus**, and it can get stuck at **saddle points**

Gradient Descent with Momentum

Training Neural Networks

- *Gradient descent with momentum* uses the momentum of the gradient for parameter optimization

Gradient Descent with Momentum

Training Neural Networks

- Parameters update in **GD with momentum** at iteration t : $\theta^t = \theta^{t-1} - V^t$
 - Where: $V^t = \beta V^{t-1} + \alpha \nabla \mathcal{L}(\theta^{t-1})$
 - I.e., $\theta^t = \theta^{t-1} - \alpha \nabla \mathcal{L}(\theta^{t-1}) - \beta V^{t-1}$
- Compare to vanilla GD: $\theta^t = \theta^{t-1} - \alpha \nabla \mathcal{L}(\theta^{t-1})$
 - Where θ^{t-1} are the parameters from the previous iteration $t - 1$
- The term V^t is called **momentum**
 - This term accumulates the gradients from the past several steps, i.e.,
$$\begin{aligned} V^t &= \beta V^{t-1} + \alpha \nabla \mathcal{L}(\theta^{t-1}) \\ &= \beta (\beta V^{t-2} + \alpha \nabla \mathcal{L}(\theta^{t-2})) + \alpha \nabla \mathcal{L}(\theta^{t-1}) \\ &= \beta^2 V^{t-2} + \beta \alpha \nabla \mathcal{L}(\theta^{t-2}) + \alpha \nabla \mathcal{L}(\theta^{t-1}) \\ &= \beta^3 V^{t-3} + \beta^2 \alpha \nabla \mathcal{L}(\theta^{t-3}) + \beta \alpha \nabla \mathcal{L}(\theta^{t-2}) + \alpha \nabla \mathcal{L}(\theta^{t-1}) \end{aligned}$$
 - This term is analogous to a momentum of a heavy ball rolling down the hill
- The parameter β is referred to as a **coefficient of momentum**
 - A typical value of the parameter β is 0.9
- This method updates the parameters θ in the direction of the weighted average of the past gradients

Nesterov Accelerated Momentum

Training Neural Networks

- **Gradient descent with Nesterov accelerated momentum**
 - Parameter update: $\theta^t = \theta^{t-1} - V^t$
 - Where: $V^t = \beta V^{t-1} + \alpha \nabla \mathcal{L}(\theta^{t-1} + \beta V^{t-1})$
 - The term $\theta^{t-1} + \beta V^{t-1}$ allows to predict the position of the parameters in the next step (i.e., $\theta^t \approx \theta^{t-1} + \beta V^{t-1}$)
 - The gradient is calculated with respect to the approximate future position of the parameters in the next iteration, θ^t , calculated at iteration $t - 1$

GD with momentum

GD with Nesterov momentum

Adam

Training Neural Networks

- **Adaptive Moment Estimation (Adam)**

- Adam combines insights from the momentum optimizers that accumulate the values of past gradients, and it also introduces new terms based on the second moment of the gradient
 - Similar to GD with momentum, Adam computes a **weighted average of past gradients** (**first moment** of the gradient), i.e., $V^t = \beta_1 V^{t-1} + (1 - \beta_1) \nabla \mathcal{L}(\theta^{t-1})$
 - Adam also computes a **weighted average of past squared gradients** (**second moment** of the gradient), i.e., $U^t = \beta_2 U^{t-1} + (1 - \beta_2) (\nabla \mathcal{L}(\theta^{t-1}))^2$
- The parameter update is: $\theta^t = \theta^{t-1} - \alpha \frac{\hat{V}^t}{\sqrt{\hat{U}^t + \epsilon}}$
 - Where: $\hat{V}^t = \frac{V^t}{1 - \beta_1}$ and $\hat{U}^t = \frac{U^t}{1 - \beta_2}$
 - The proposed default values are $\beta_1 = 0.9$, $\beta_2 = 0.999$, and $\epsilon = 10^{-8}$
- Other commonly used optimization methods include:
 - Adagrad, Adadelata, RMSprop, Nadam, etc.
 - Most commonly used optimizers nowadays are Adam and SGD with momentum

Learning Rate

Training Neural Networks

- *Learning rate*

- The gradient tells us the direction in which the loss has the steepest rate of increase, but it does not tell us how far along the opposite direction we should step
- Choosing the learning rate (also called the **step size**) is one of the most important hyper-parameter settings for NN training

Learning Rate

Training Neural Networks

- Training loss for different learning rates
 - High learning rate: the loss increases or plateaus too quickly
 - Low learning rate: the loss decreases too slowly (takes many epochs to reach a solution)

Learning Rate Scheduling

Training Neural Networks

- **Learning rate scheduling** is applied to change the values of the learning rate during the training
 - **Annealing** is reducing the learning rate over time (a.k.a. learning rate decay)
 - Approach 1: reduce the learning rate by some factor **every few epochs**
 - Typical values: reduce the learning rate by a half every 5 epochs, or divide by 10 every 20 epochs
 - Approach 2: **exponential** or **cosine decay** gradually reduce the learning rate over time
 - Approach 3: reduce the learning rate by a constant (e.g., by half) whenever the **validation loss stops improving**
 - In TensorFlow: `tf.keras.callbacks.ReduceLROnPlateau()`
 - Monitor: validation loss, factor: 0.1 (i.e., divide by 10), patience: 10 (how many epochs to wait before applying it), Minimum learning rate: 1e-6 (when to stop)
 - **Warmup** is gradually increasing the learning rate initially, and afterward let it cool down until the end of the training

Exponential decay

Cosine decay

Warmup

Vanishing Gradient Problem

Training Neural Networks

- In some cases, during training, the gradients can become either very small (vanishing gradients) or very large (exploding gradients)
 - They result in very small or very large update of the parameters
 - Solutions: change learning rate, ReLU activations, regularization, LSTM units in RNNs

Generalization

Generalization

- **Underfitting**

- The model is too “simple” to represent all the relevant class characteristics
- E.g., model with too few parameters
- Produces high error on the training set and high error on the validation set

- **Overfitting**

- The model is too “complex” and fits irrelevant characteristics (noise) in the data
- E.g., model with too many parameters
- Produces low error on the training error and high error on the validation set

Overfitting

Generalization

- Overfitting – a model with high capacity fits the noise in the data instead of the underlying relationship

- The model may fit the training data very well, but fails to **generalize** to new examples (test or validation data)

Regularization: Weight Decay

Regularization

- ℓ_2 weight decay

- A regularization term that penalizes large weights is added to the loss function

$$\mathcal{L}_{reg}(\theta) = \underbrace{\mathcal{L}(\theta)}_{\text{Data loss}} + \underbrace{\lambda \sum_k \theta_k^2}_{\text{Regularization loss}}$$

- For every weight in the network, we add the regularization term to the loss value
 - During gradient descent parameter update, every weight is decayed linearly toward zero
- The **weight decay coefficient** λ determines how dominant the regularization is during the gradient computation

Regularization: Weight Decay

Regularization

- Effect of the decay coefficient λ
 - Large weight decay coefficient \rightarrow penalty for weights with large values

Regularization: Weight Decay

Regularization

- ℓ_1 *weight decay*

- The regularization term is based on the ℓ_1 norm of the weights

$$\mathcal{L}_{reg}(\theta) = \mathcal{L}(\theta) + \lambda \sum_k |\theta_k|$$

- ℓ_1 weight decay is less common with NN
 - Often performs worse than ℓ_2 weight decay
- It is also possible to combine ℓ_1 and ℓ_2 regularization
 - Called **elastic net regularization**

$$\mathcal{L}_{reg}(\theta) = \mathcal{L}(\theta) + \lambda_1 \sum_k |\theta_k| + \lambda_2 \sum_k \theta_k^2$$

Regularization: Dropout

Regularization

- **Dropout**

- Randomly drop units (along with their connections) during training
- Each unit is retained with a fixed **dropout rate p** , independent of other units
- The hyper-parameter p needs to be chosen (tuned)
 - Often, between 20% and 50% of the units are dropped

Regularization: Dropout

Regularization

- Dropout is a kind of ensemble learning
 - Using one mini-batch to train one network with a slightly different architecture

Regularization: Early Stopping

Regularization

- *Early-stopping*

- During model training, use a **validation set**
 - E.g., validation/train ratio of about 25% to 75%
- Stop when the validation accuracy (or loss) has not improved after n epochs
 - The parameter n is called **patience**

Batch Normalization

Regularization

- **Batch normalization layers** act similar to the data preprocessing steps mentioned earlier
 - They calculate the mean μ and variance σ of a batch of input data, and normalize the data x to a zero mean and unit variance
 - I.e., $\hat{x} = \frac{x - \mu}{\sigma}$
- **BatchNorm layers** alleviate the problems of proper initialization of the parameters and hyper-parameters
 - Result in faster convergence training, allow larger learning rates
 - Reduce the internal covariate shift
- BatchNorm layers are inserted immediately after convolutional layers or fully-connected layers, and before activation layers
 - They are very common with convolutional NNs

Hyper-parameter Tuning

Hyper-parameter Tuning

- Training NNs can involve setting many *hyper-parameters*
- The most common hyper-parameters include:
 - Number of layers, and number of neurons per layer
 - Initial learning rate
 - Learning rate decay schedule (e.g., decay constant)
 - Optimizer type
- Other hyper-parameters may include:
 - Regularization parameters (ℓ_2 penalty, dropout rate)
 - Batch size
 - Activation functions
 - Loss function
- Hyper-parameter tuning can be time-consuming for larger NNs

Hyper-parameter Tuning

Hyper-parameter Tuning

- **Grid search**
 - Check all values in a range with a step value
- **Random search**
 - Randomly sample values for the parameter
 - Often preferred to grid search
- **Bayesian hyper-parameter optimization**
 - Is an active area of research

k -Fold Cross-Validation

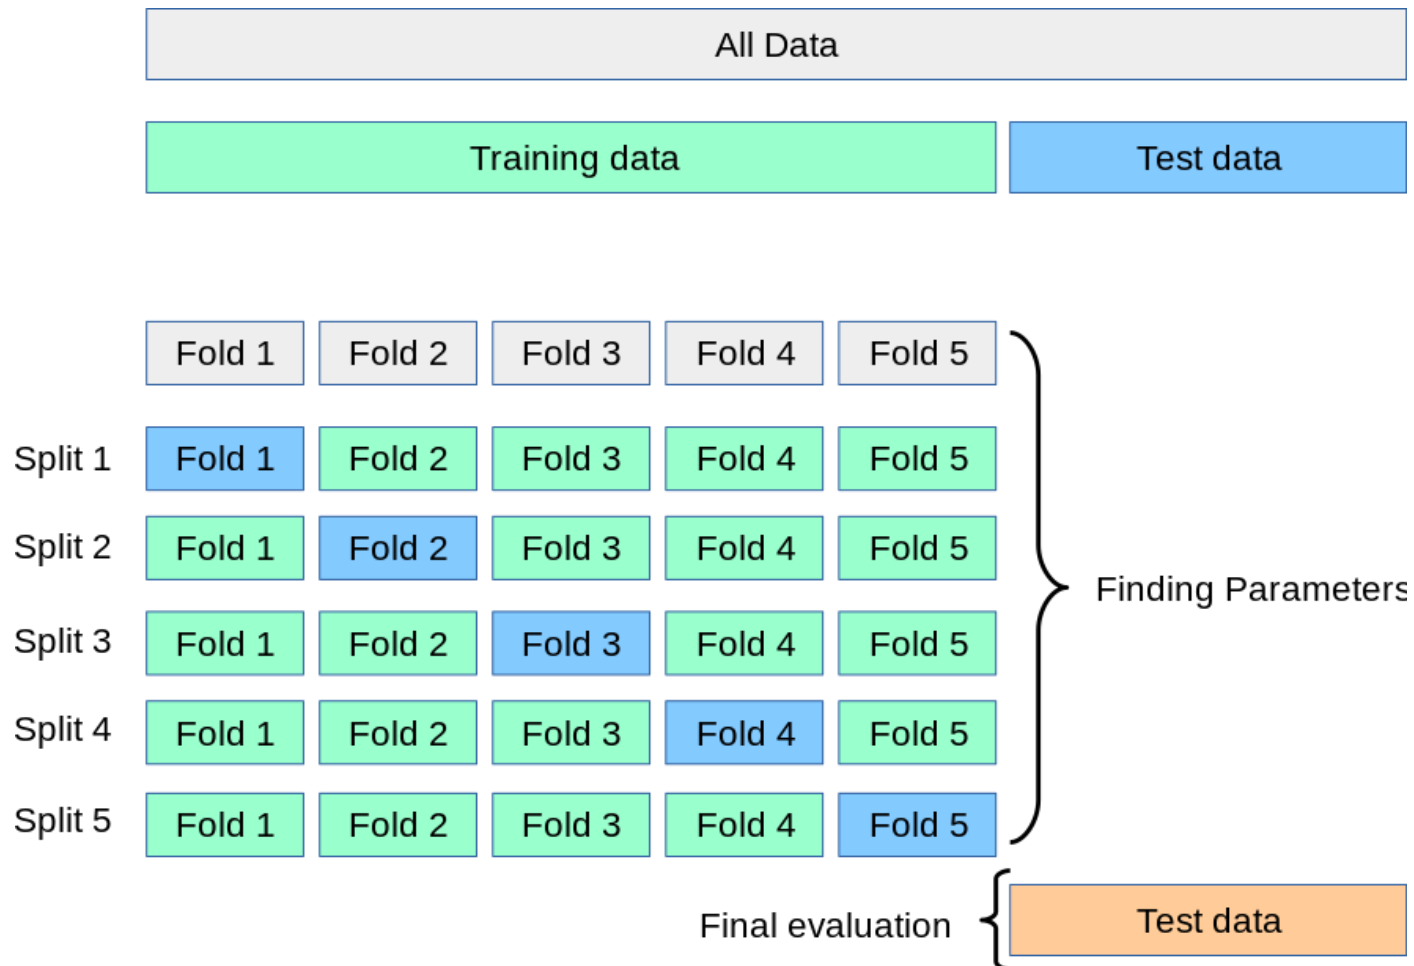

k-Fold Cross-Validation

- Using *k-fold cross-validation* for hyper-parameter tuning is common when the size of the training data is small
 - It also leads to a better and less noisy estimate of the model performance by averaging the results across several folds
- E.g., 5-fold cross-validation (see the figure on the next slide)
 1. Split the train data into 5 equal folds
 2. First use folds 2-5 for training and fold 1 for validation
 3. Repeat by using fold 2 for validation, then fold 3, fold 4, and fold 5
 4. Average the results over the 5 runs (for reporting purposes)
 5. Once the best hyper-parameters are determined, evaluate the model on the test data

k -Fold Cross-Validation

k-Fold Cross-Validation

- Illustration of a 5-fold cross-validation

Ensemble Learning

Ensemble Learning

- **Ensemble learning** is training multiple classifiers separately and combining their predictions
 - Ensemble learning often outperforms individual classifiers
 - Better results obtained with higher model variety in the ensemble
 - **Bagging** (bootstrap aggregating)
 - Randomly draw subsets from the training set (i.e., bootstrap samples)
 - Train separate classifiers on each subset of the training set
 - Perform classification based on the average vote of all classifiers
 - **Boosting**
 - Train a classifier, and apply weights on the training set (apply **higher weights on misclassified examples**, focus on “hard examples”)
 - Train new classifier, reweight training set according to prediction error
 - Repeat
 - Perform classification based on weighted vote of the classifiers

Deep vs Shallow Networks

Deep vs Shallow Networks

- **Deeper networks** perform better than shallow networks
 - But only up to some limit: after a certain number of layers, the performance of deeper networks plateaus

Shallow
NN

Deep
NN

Convolutional Neural Networks (CNNs)

Convolutional Neural Networks

- **Convolutional neural networks** (CNNs) were primarily designed for image data
- CNNs use **a convolutional operator** for extracting data features
 - Allows **parameter sharing**
 - Efficient to train
 - Have **less parameters** than NNs with fully-connected layers
- CNNs are **robust to spatial translations** of objects in images
- A convolutional filter slides (i.e., convolves) across the image

Convolutional Neural Networks (CNNs)

Convolutional Neural Networks

- When the convolutional filters are scanned over the image, they capture useful features
 - E.g., edge detection by convolutions

Filter 
$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Input Image

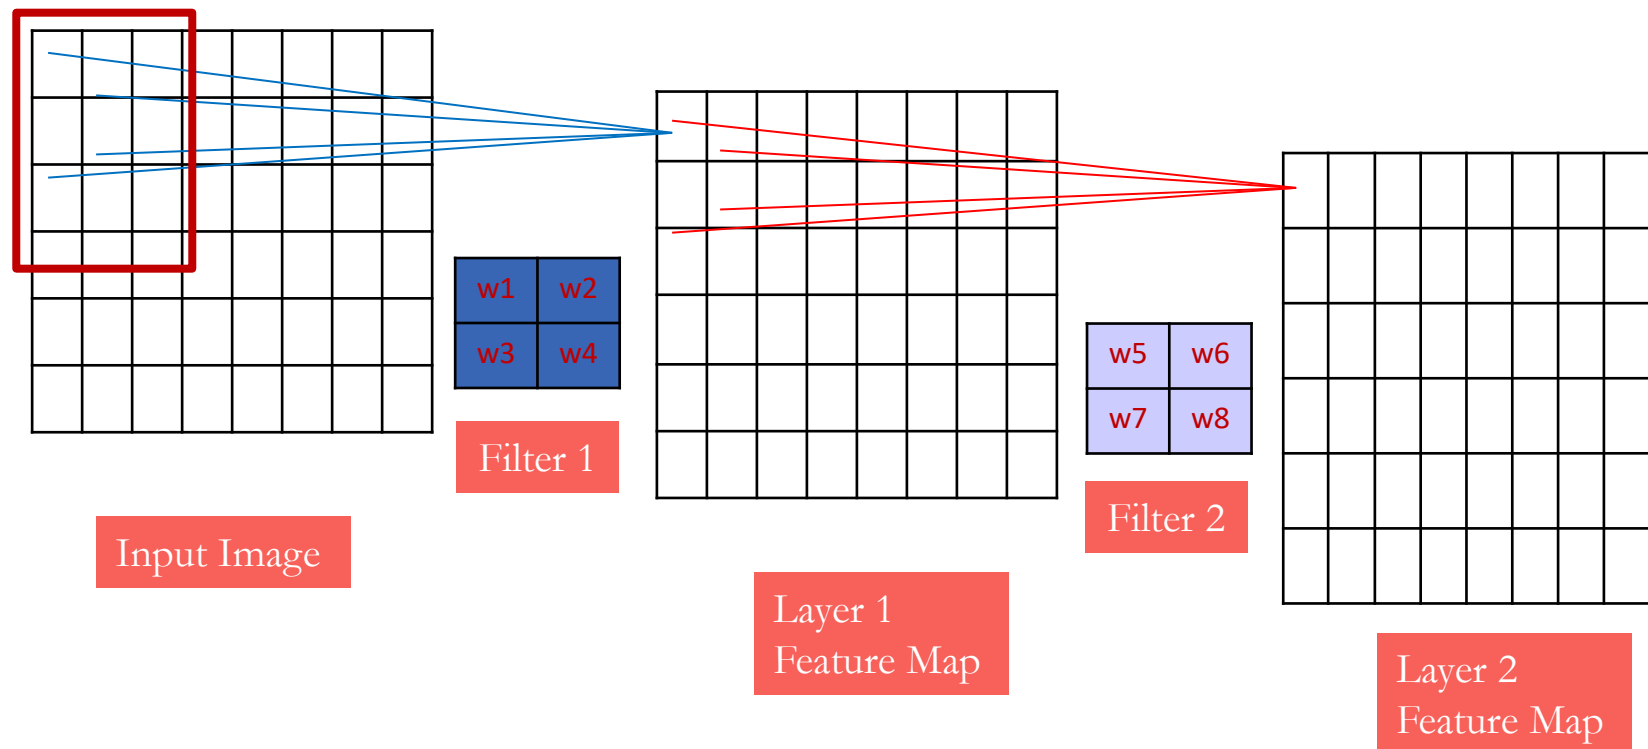

Convolved Image

Convolutional Neural Networks (CNNs)

Convolutional Neural Networks

- In CNNs, hidden units in a layer are only connected to a small region of the layer before it (called local **receptive field**)
 - The depth of each **feature map** corresponds to the number of convolutional filters used at each layer

Convolutional Neural Networks (CNNs)

Convolutional Neural Networks

- **Max pooling**: reports the maximum output within a rectangular neighborhood
- **Average pooling**: reports the average output of a rectangular neighborhood
- Pooling layers reduce the spatial size of the feature maps
 - Reduce the number of parameters, prevent overfitting

1	3	5	3

Output Matrix

Convolutional Neural Networks (CNNs)

Convolutional Neural Networks

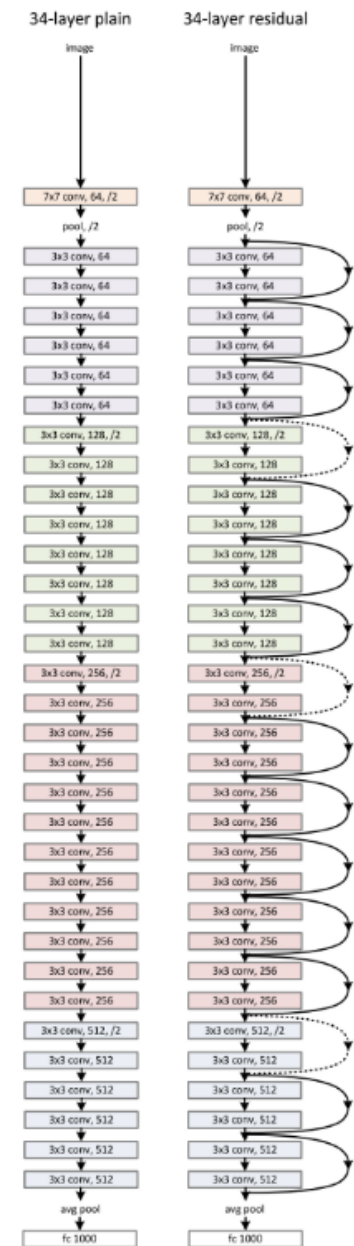

- Feature extraction architecture
 - After 2 convolutional layers, a max-pooling layer reduces the size of the feature maps (typically by 2)
 - A fully convolutional and a softmax layers are added last to perform classification

Residual CNNs

Convolutional Neural Networks

- **Residual networks** (ResNets)
 - Introduce “identity” **skip connections**
 - Layer inputs are propagated and added to the layer output
 - Mitigate the problem of vanishing gradients during training
 - Allow training very deep NN (with over 1,000 layers)
 - Several ResNet variants exist: 18, 34, 50, 101, 152, and 200 layers
 - Are used as base models of other state-of-the-art NNs
 - Other similar models: ResNeXT, DenseNet

Recurrent Neural Networks (RNNs)

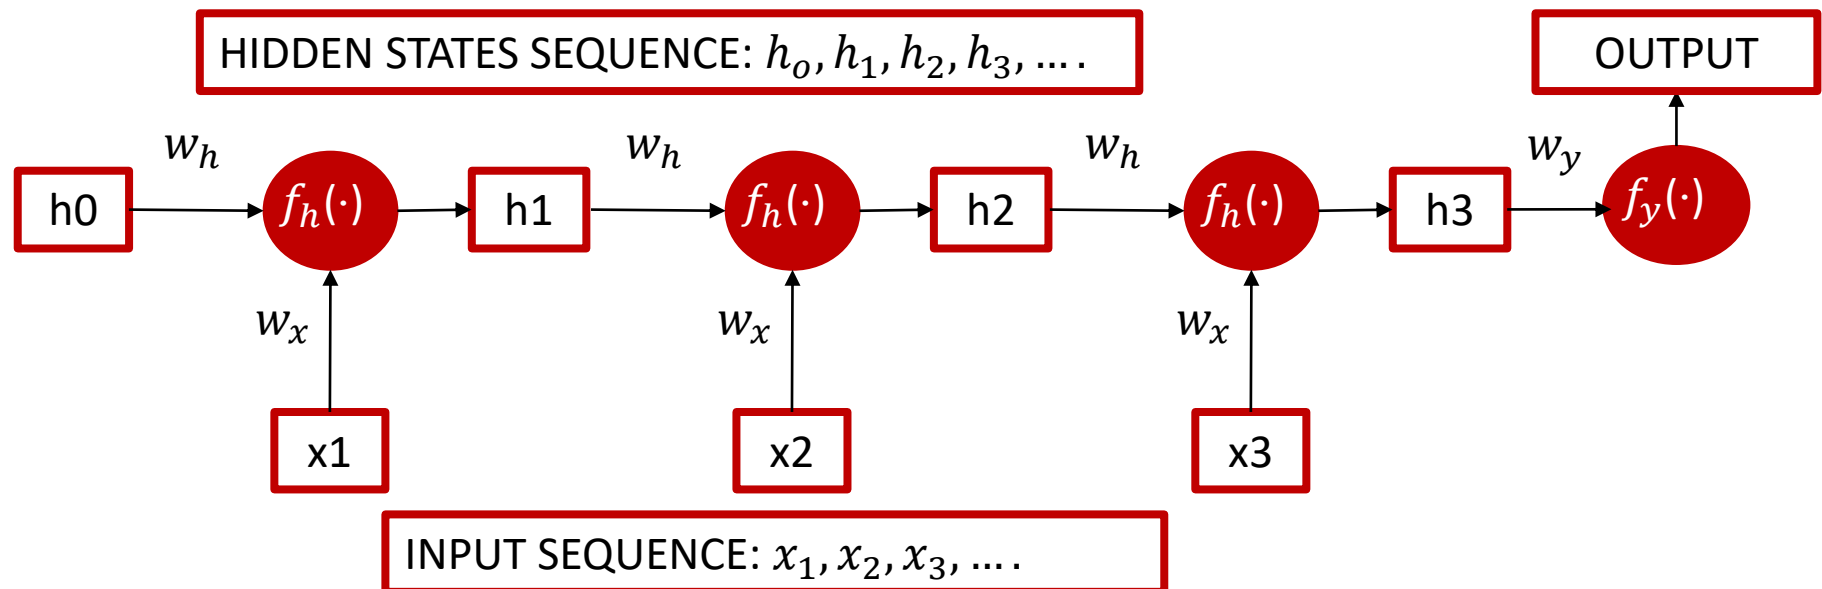

Recurrent Neural Networks

- **Recurrent NNs** are used for modeling **sequential data** and data with varying length of inputs and outputs
 - Videos, text, speech, DNA sequences, human skeletal data
- RNNs introduce recurrent connections between the neurons
 - This allows processing sequential data one element at a time by selectively passing information across a sequence
 - Memory of the previous inputs is stored in the model's internal state and affect the model predictions
 - Can capture correlations in sequential data
- RNNs use **backpropagation-through-time** for training
- RNNs are more sensitive to the vanishing gradient problem than CNNs

Recurrent Neural Networks (RNNs)

Recurrent Neural Networks

- RNN use same set of weights w_h and w_x **across all time steps**
 - A sequence of **hidden states** $\{h_0, h_1, h_2, h_3, \dots\}$ is learned, which represents the memory of the network
 - The hidden state at step t , $h(t)$, is calculated based on the previous hidden state $h(t-1)$ and the input at the current step $x(t)$, i.e., $h(t) = f_h(w_h * h(t-1) + w_x * x(t))$
 - The function $f_h(\cdot)$ is a nonlinear activation function, e.g., ReLU or tanh
- RNN shown rolled over time

Recurrent Neural Networks (RNNs)

Recurrent Neural Networks

- RNNs can have one of many inputs and one of many outputs

Bidirectional RNNs

Recurrent Neural Networks

- **Bidirectional RNNs** incorporate both forward and backward passes through sequential data
 - The output may not only depend on the previous elements in the sequence, but also on future elements in the sequence
 - It resembles two RNNs stacked on top of each other

$$\vec{h}_t = \sigma(\vec{W}^{(hh)}\vec{h}_{t-1} + \vec{W}^{(hx)}x_t)$$

$$\overleftarrow{h}_t = \sigma(\overleftarrow{W}^{(hh)}\overleftarrow{h}_{t+1} + \overleftarrow{W}^{(hx)}x_t)$$

$$y_t = f\left(\begin{bmatrix} \vec{h}_t \\ \overleftarrow{h}_t \end{bmatrix}\right)$$

Outputs both past and future elements

LSTM Networks

Recurrent Neural Networks

- *Long Short-Term Memory (LSTM)* networks are a variant of RNNs
- LSTM mitigates the vanishing/exploding gradient problem
 - Solution: a **Memory Cell**, updated at each step in the sequence
- Three gates control the flow of information to and from the Memory Cell
 - **Input Gate**: protects the current step from irrelevant inputs
 - **Output Gate**: prevents current step from passing irrelevant information to later steps
 - **Forget Gate**: limits information passed from one cell to the next
- Most modern RNN models use either LSTM units or other more advanced types of recurrent units (e.g., GRU units)

LSTM Networks

Recurrent Neural Networks

- LSTM cell
 - Input gate, output gate, forget gate, memory cell
 - LSTM can learn long-term correlations within data sequences

$$\mathbf{i}^{(k)} = \sigma(\mathbf{W}_{oi} \mathbf{o}_m^{(k)} + \mathbf{W}_{hi} \mathbf{h}^{(k-1)} + \mathbf{b}_i)$$

$$\mathbf{f}^{(k)} = \sigma(\mathbf{W}_{of} \mathbf{o}_m^{(k)} + \mathbf{W}_{hf} \mathbf{h}^{(k-1)} + \mathbf{b}_f)$$

$$\mathbf{q}^{(k)} = \sigma(\mathbf{W}_{oq} \mathbf{o}_m^{(k)} + \mathbf{W}_{hq} \mathbf{h}^{(k-1)} + \mathbf{b}_q)$$

$$\mathbf{c}^{(k)} = \mathbf{f}^{(k)} \mathbf{c}^{(k-1)} + \mathbf{i}^{(k)} \sigma(\mathbf{W}_{oc} \mathbf{o}_m^{(k)} + \mathbf{W}_{hc} \mathbf{h}^{(k-1)} + \mathbf{b}_c)$$

$$\mathbf{h}^{(k)} = \mathbf{q}^{(k)} \tanh(\mathbf{c}^{(k)})$$
